CloudShield

Secure 3-Tier Architecture on AWS

Final Project Documentation

Implementation Phases • Evidence Screenshots • Resolved Problems

AWS Region: Asia Pacific (Mumbai) — ap-south-1
Prepared from the supplied CloudShield infrastructure screenshot PDF and the two dedicated troubleshooting references.

How to read this document

The report follows the original implementation evidence in phase order. Each phase explains what was configured, why it was needed, and how it fits into CloudShield. The screenshots belonging to that phase are placed immediately after the written explanation.

The last two sections document the two problems separately: (1) replacing the unencrypted backend EBS volume with an encrypted replacement, and (2) resolving Systems Manager Patch Manager access and output-delivery issues. The dedicated problem PDFs were supplied as reference material; the corresponding original screenshots are also included from the stated page ranges in CloudShield-Final-PDF.

Evidence standard: a console screenshot can show that a resource or setting was configured. A successful functional test is only claimed where the supplied evidence records the result. The architecture diagram expresses the intended design and is not, by itself, proof that an application is running.

Contents

- Project overview and design goals
- Phase 1 — VPC, subnets, gateways, and route tables
- Phase 2 — Security groups, IAM identity, initial 'CloudShiled-S3-Bucket', and SNS configuration
- Phase 3 — Database subnet group and RDS, backend-EC2 instance
- Phase 4 — EC2 web tier, launch template, ALB, target group, and ASG
- Phase 5 — Monitoring, alarms, and budget alerts
- Phase 6 — Account-level S3 Block Public Access, always-encrypted EBS volumes, Access Analyzer, CloudTrail and VPC Flow Logs with S3 destinations, EventBridge, and EC2 metadata options
- Phase 7 — Add-ons in 'cloudshield-s3-bucket', Systems Manager & Patch Manager
- Problem 1 — EBS volume encryption migration
- Problem 2 — Patch Manager policy and output-delivery troubleshooting
- Final outcome and operational notes

Project overview

CloudShield is an infrastructure-focused AWS project in ap-south-1 (Mumbai). It separates public-facing web resources from a private backend and database tier, applies security-group boundaries, uses EC2 IAM roles, provides controlled S3 access, and adds monitoring, audit logging, and Systems Manager operations.

Objectives

• Build a VPC with separate public and private subnets across two Availability Zones.

• Place internet-facing access through an Application Load Balancer and distribute web capacity across two AZs.

• Keep the backend EC2 instance private and manage it through Systems Manager Session Manager rather than inbound SSH.

• Use RDS as a private managed database tier.

• Control S3 access using IAM permissions, bucket protections, and an S3 Gateway Endpoint policy.

• Collect operational metrics and alerts with CloudWatch/SNS, account activity with CloudTrail, and traffic metadata with VPC Flow Logs.

• Configure Patch Manager scanning for the Linux EC2 nodes and deliver output to a dedicated S3 bucket.

Final architecture reference

The final architecture image supplied by the project owner shows: users → Internet Gateway → internet-facing ALB → two web EC2 instances; web tier → private backend; backend → RDS MySQL on TCP 3306; backend S3 access through an S3 Gateway Endpoint; private-subnet outbound access through NAT where required; and CloudWatch/SNS, CloudTrail, VPC Flow Logs, and Systems Manager for operations and auditing.

Component	Project configuration / purpose
Region and VPC	ap-south-1; MyVPC — 10.0.0.0/16
Public subnet AZ1	10.0.1.0/24
Private subnet AZ1	10.0.2.0/24 — backend EC2
Private subnet AZ2	10.0.3.0/24 — RDS subnet-group coverage
Public subnet AZ2	10.0.4.0/24
Internet Gateway	my-IGW
NAT Gateway	my-NAT-gateway
S3 Gateway Endpoint	Private S3 route via the S3 prefix list; endpoint policy filters permitted S3 actions/resources
Web tier	cloudshield-web-asg; ALB and cloudshield-web-tg; diagram shows min 2, max 3, CPU target tracking 60%
Database	cloudshield-rds; architecture diagram labels MySQL 8.4, encrypted, backups enabled, Single-AZ, private subnet group

> The diagram labels HTTP 80 at the ALB and port 3000 between web and backend. These are the design's labelled flows; do not infer that a live application endpoint is running unless independently tested.

Phase 1 — VPC, subnets, gateways, and route tables

The foundation is the VPC and its subnet layout. MyVPC uses 10.0.0.0/16. Two public subnets and two private subnets are distributed across two Availability Zones. The Internet Gateway provides internet routing for public resources. Route tables decide which next hop is used for traffic leaving each subnet.

Why this phase matters

Separating public and private subnets creates a basic network trust boundary. The ALB and web tier need a public-facing path; the backend and database should not be directly exposed to the internet. The NAT Gateway gives private resources outbound internet access when needed, while the S3 Gateway Endpoint provides a private route for S3 traffic that matches the endpoint route.

What was configured

• Public subnet AZ1: 10.0.1.0/24; public subnet AZ2: 10.0.4.0/24.

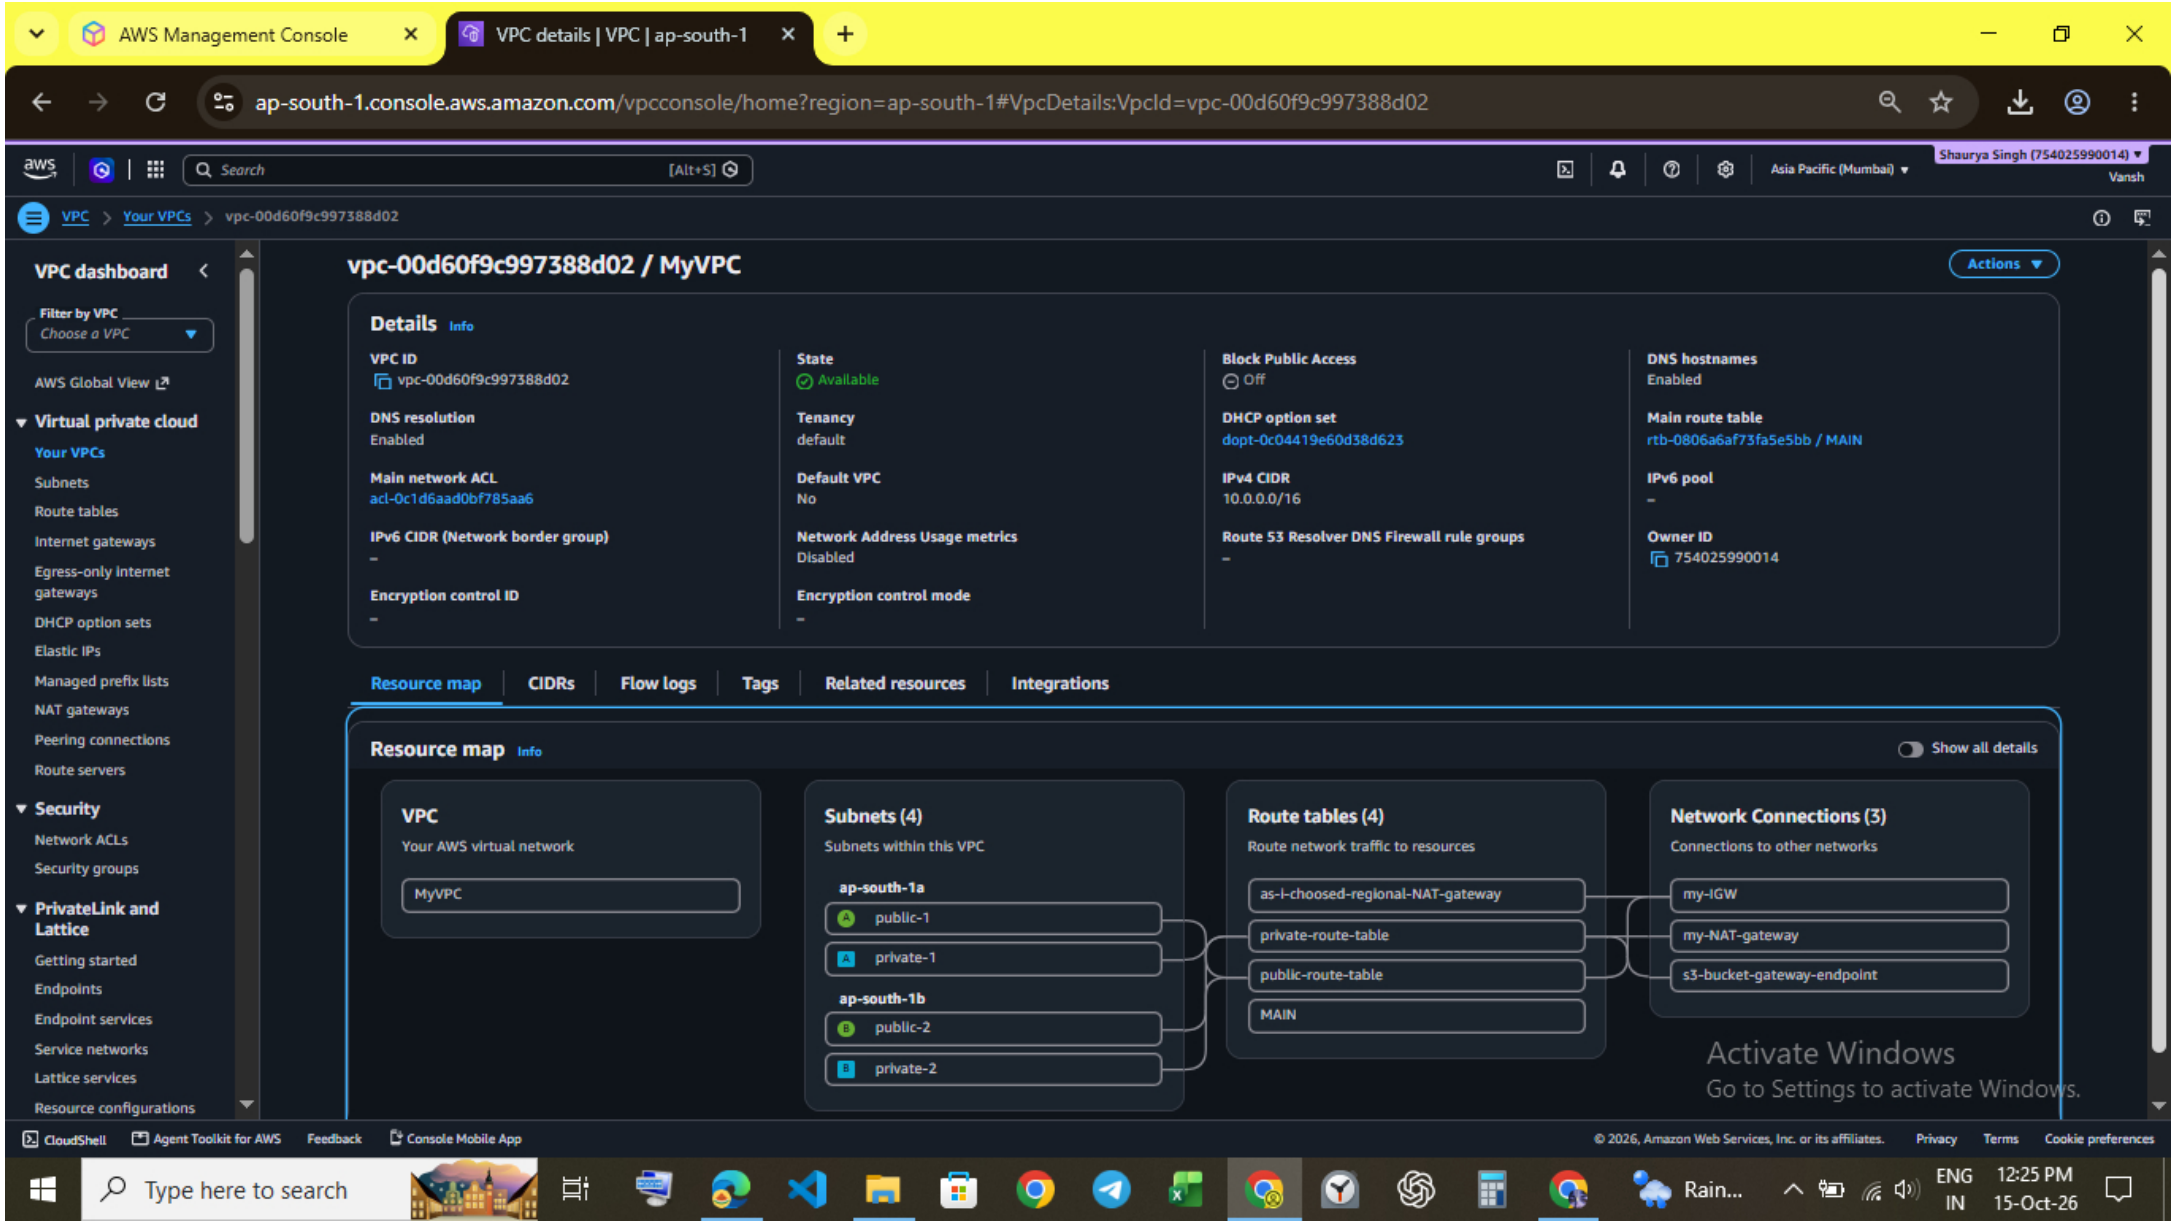

• Private subnet AZ1: 10.0.2.0/24; private subnet AZ2: 10.0.3.0/24.

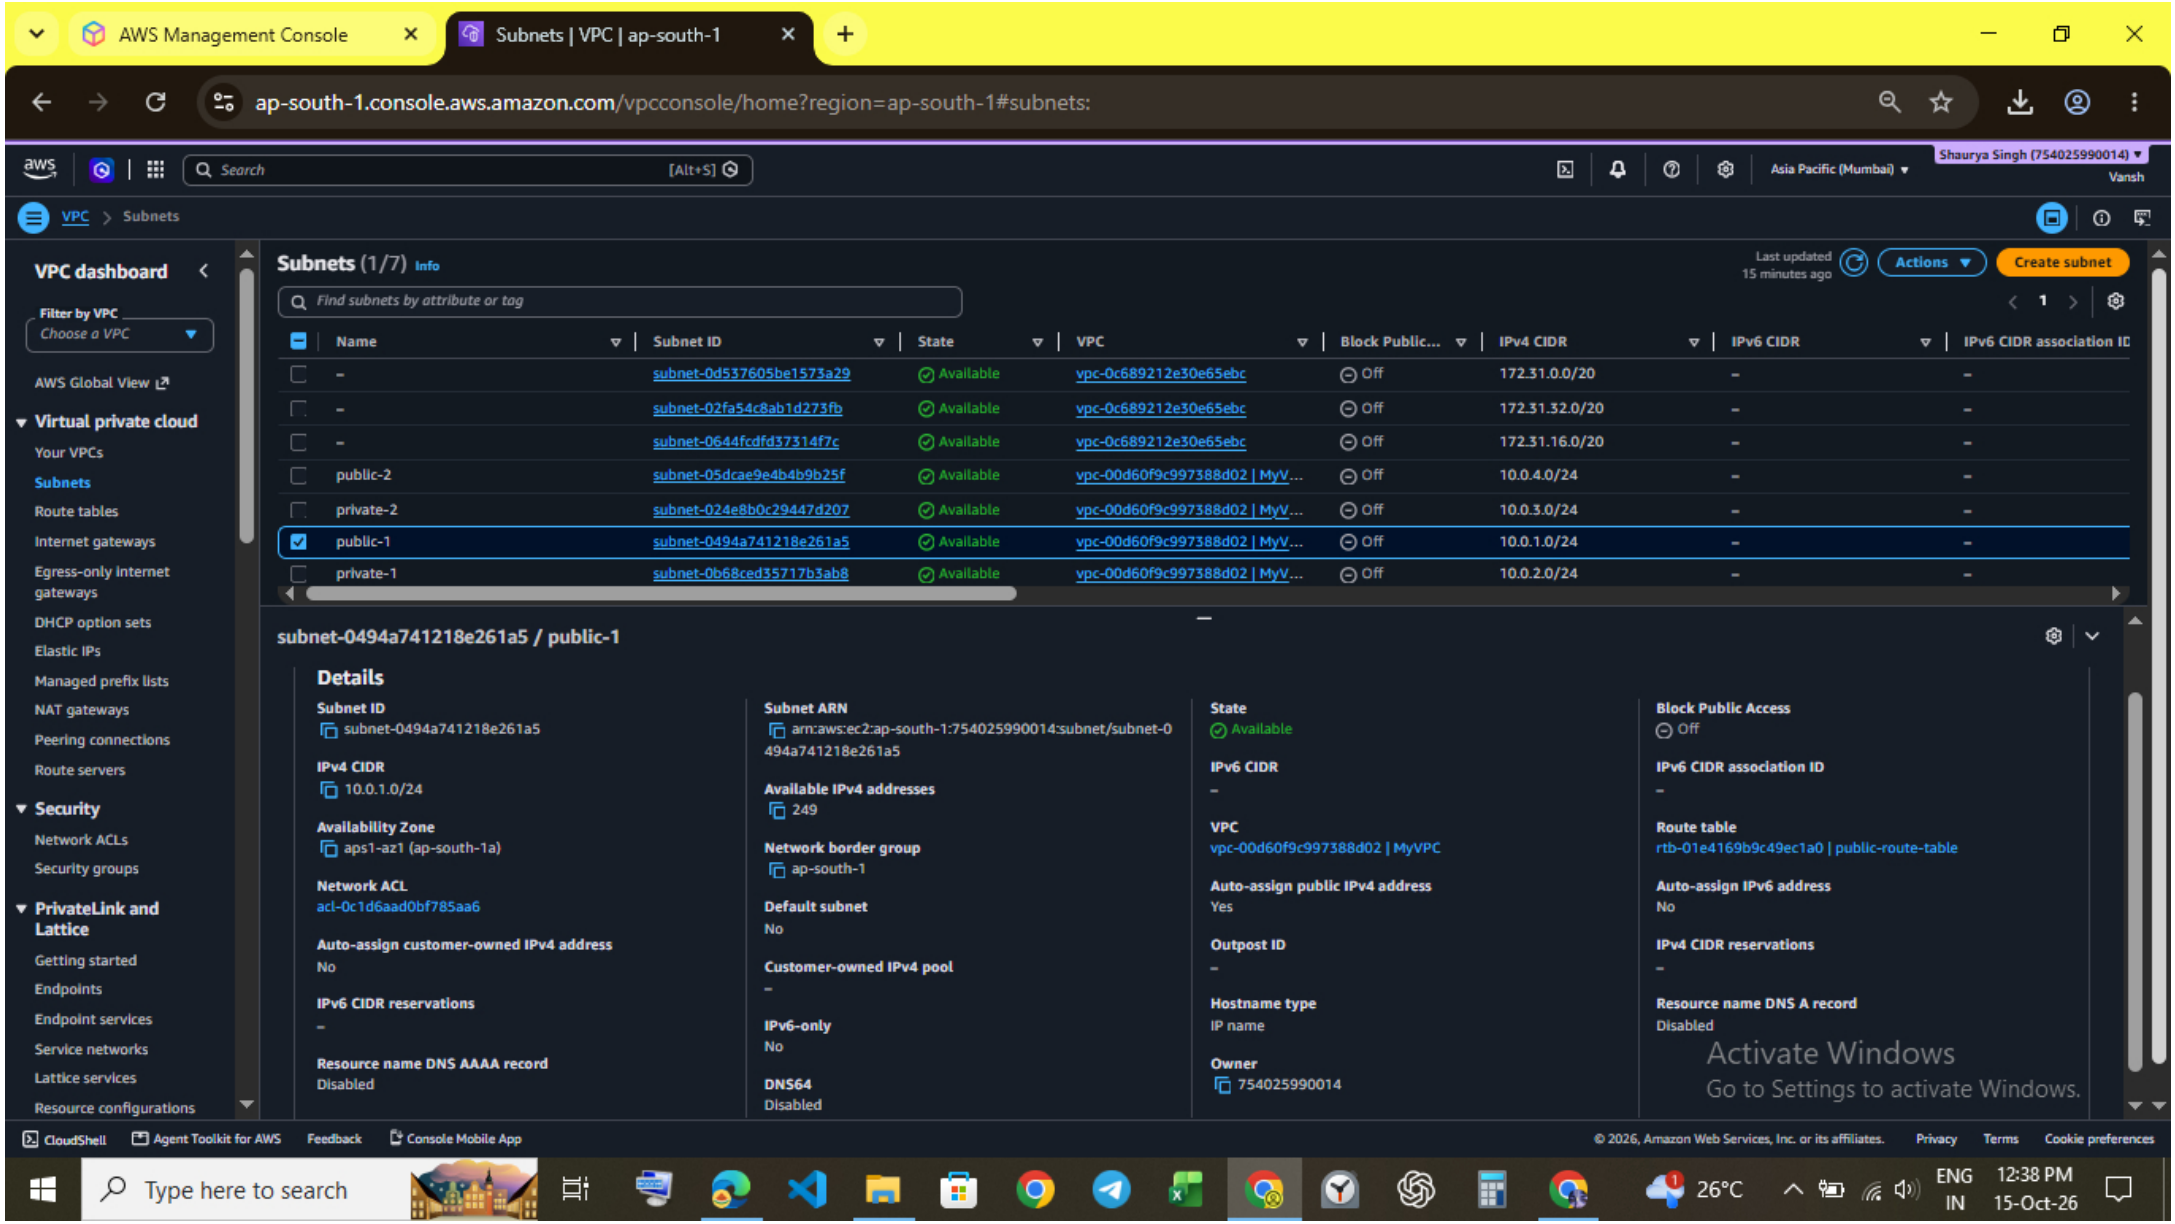

• Attached my-IGW and configured the public route path.

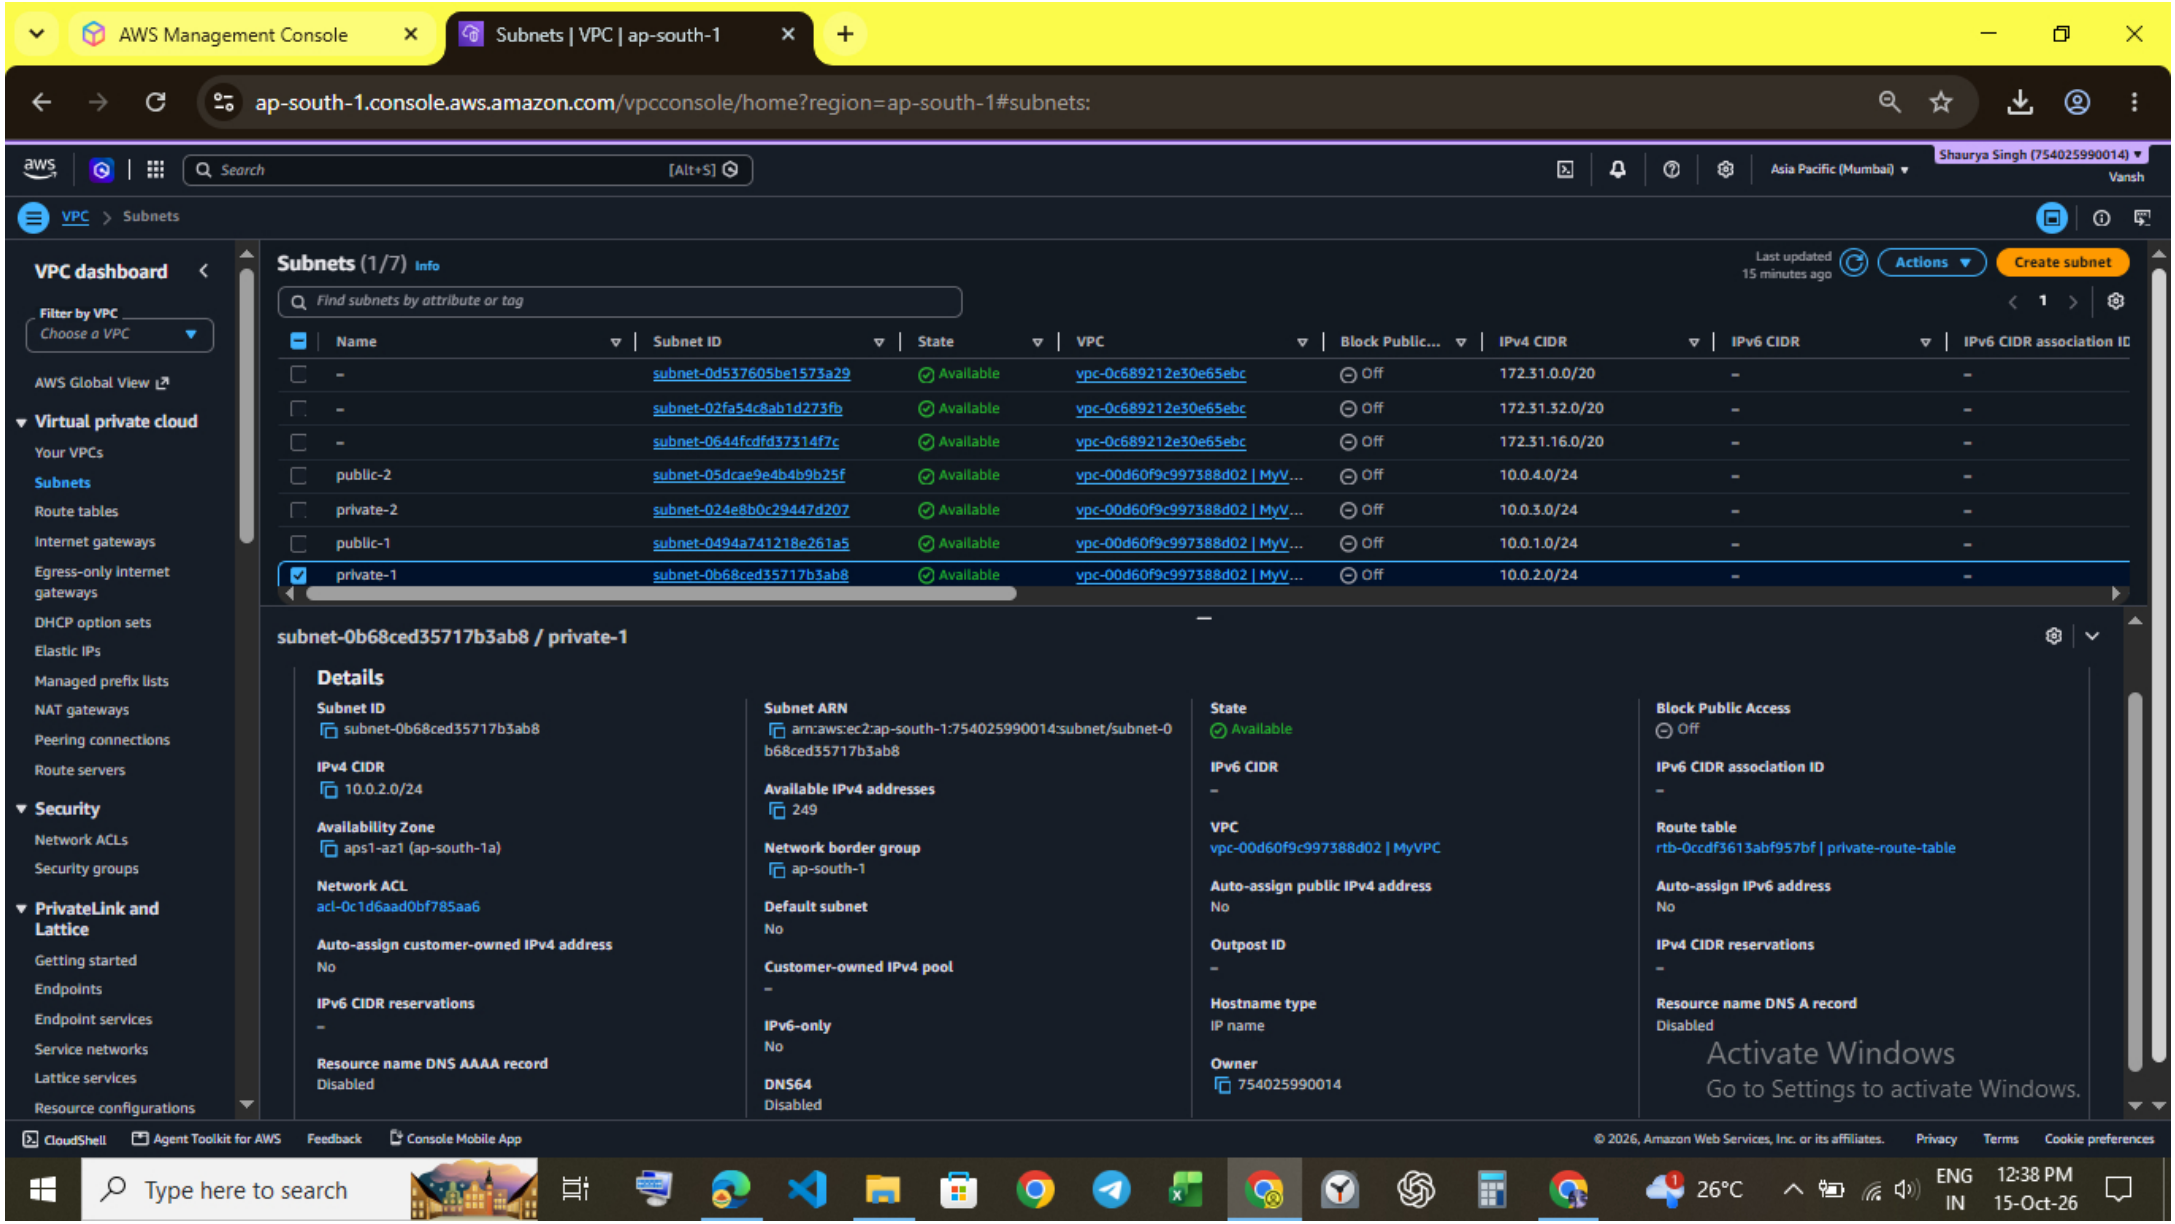

• Configured private-subnet outbound routing through my-NAT-gateway and an S3 Gateway Endpoint route.

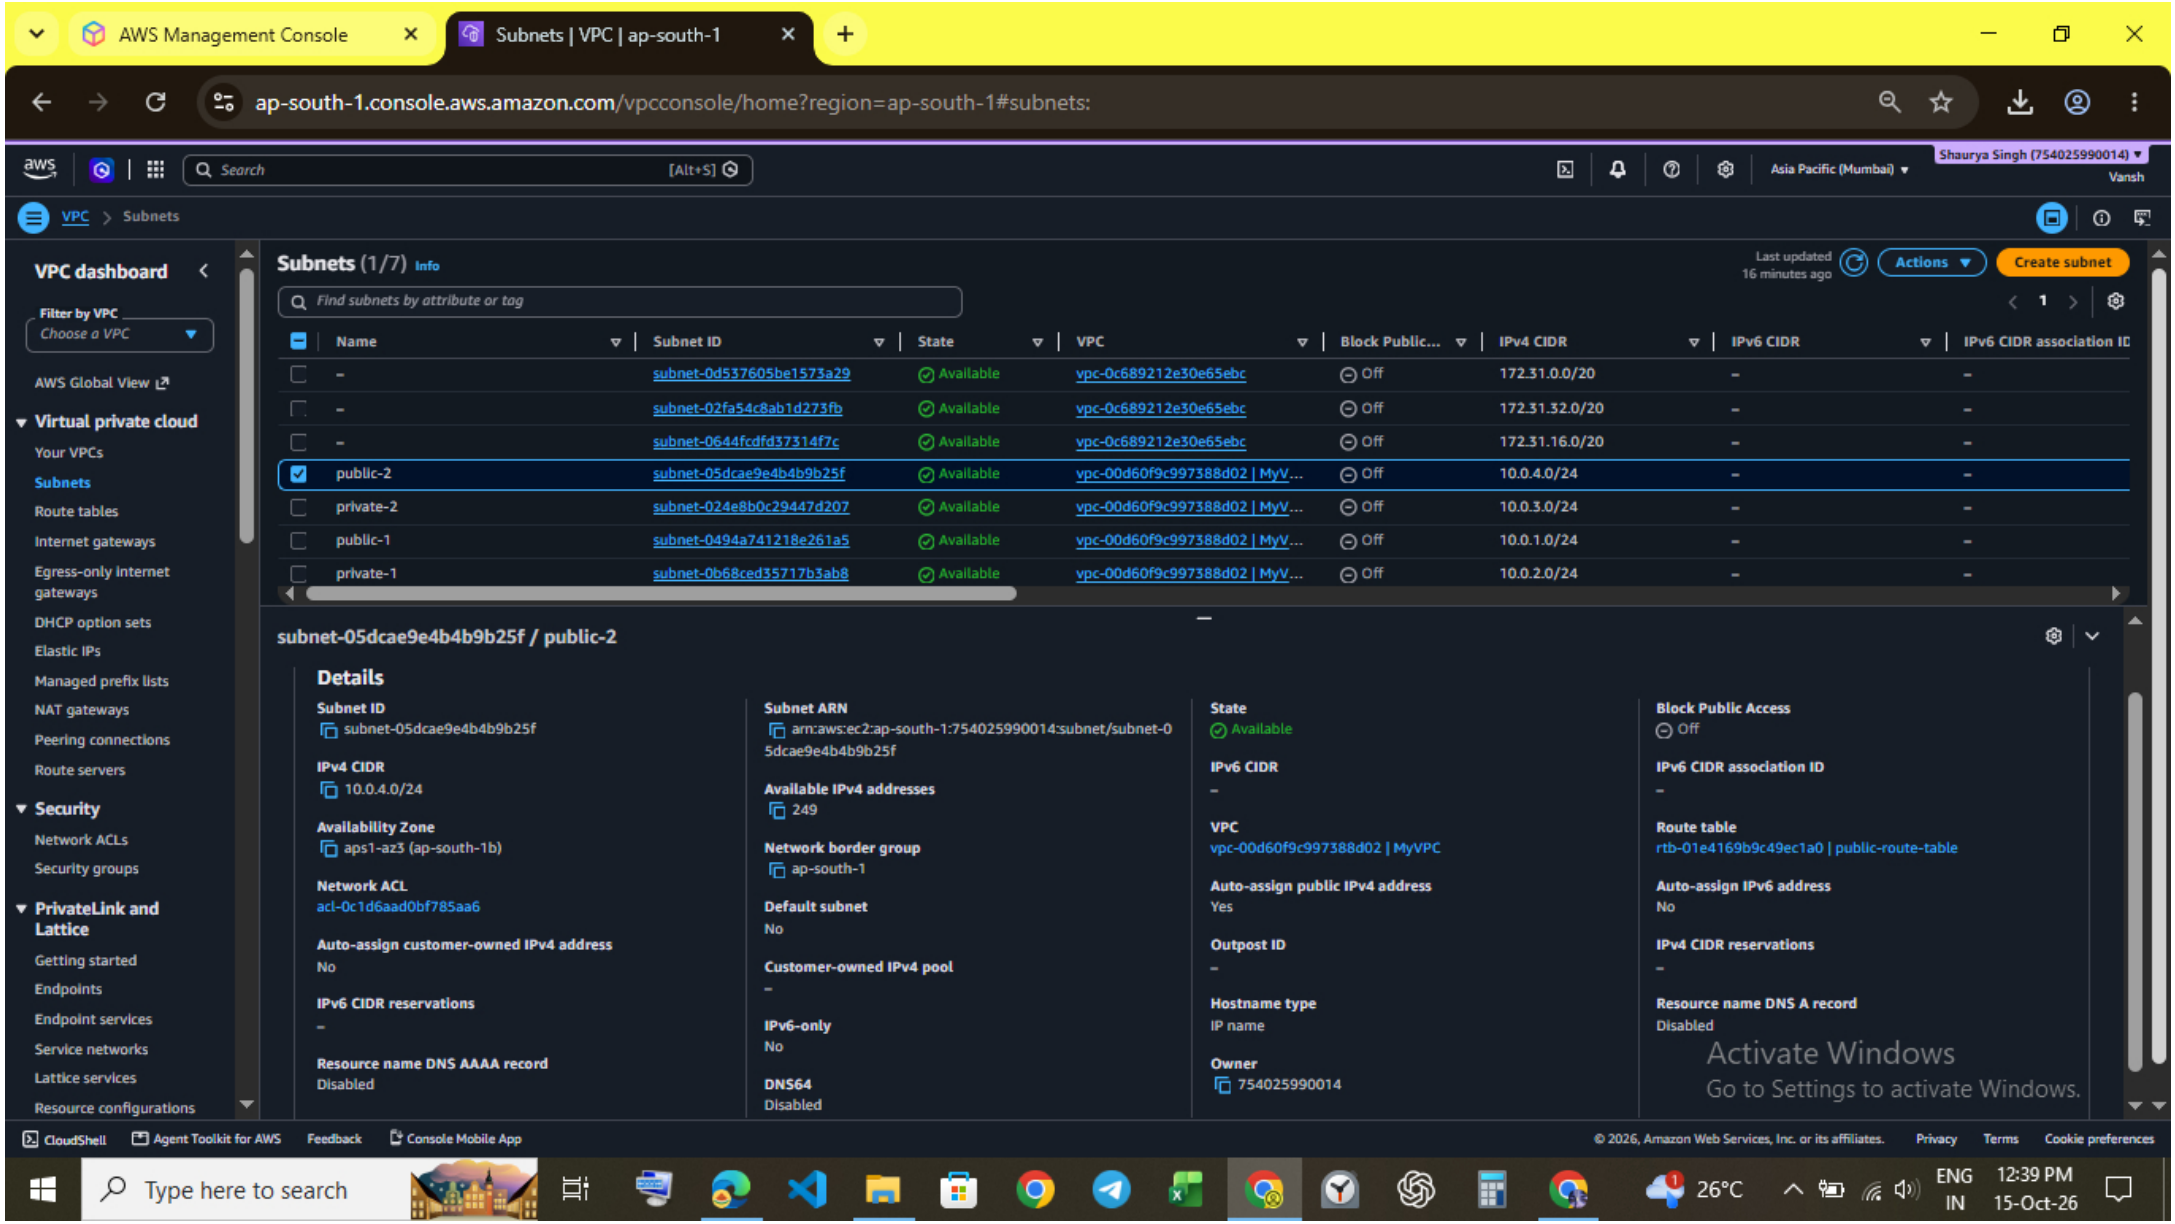

• Checked the route-table configuration and associated subnet routing.

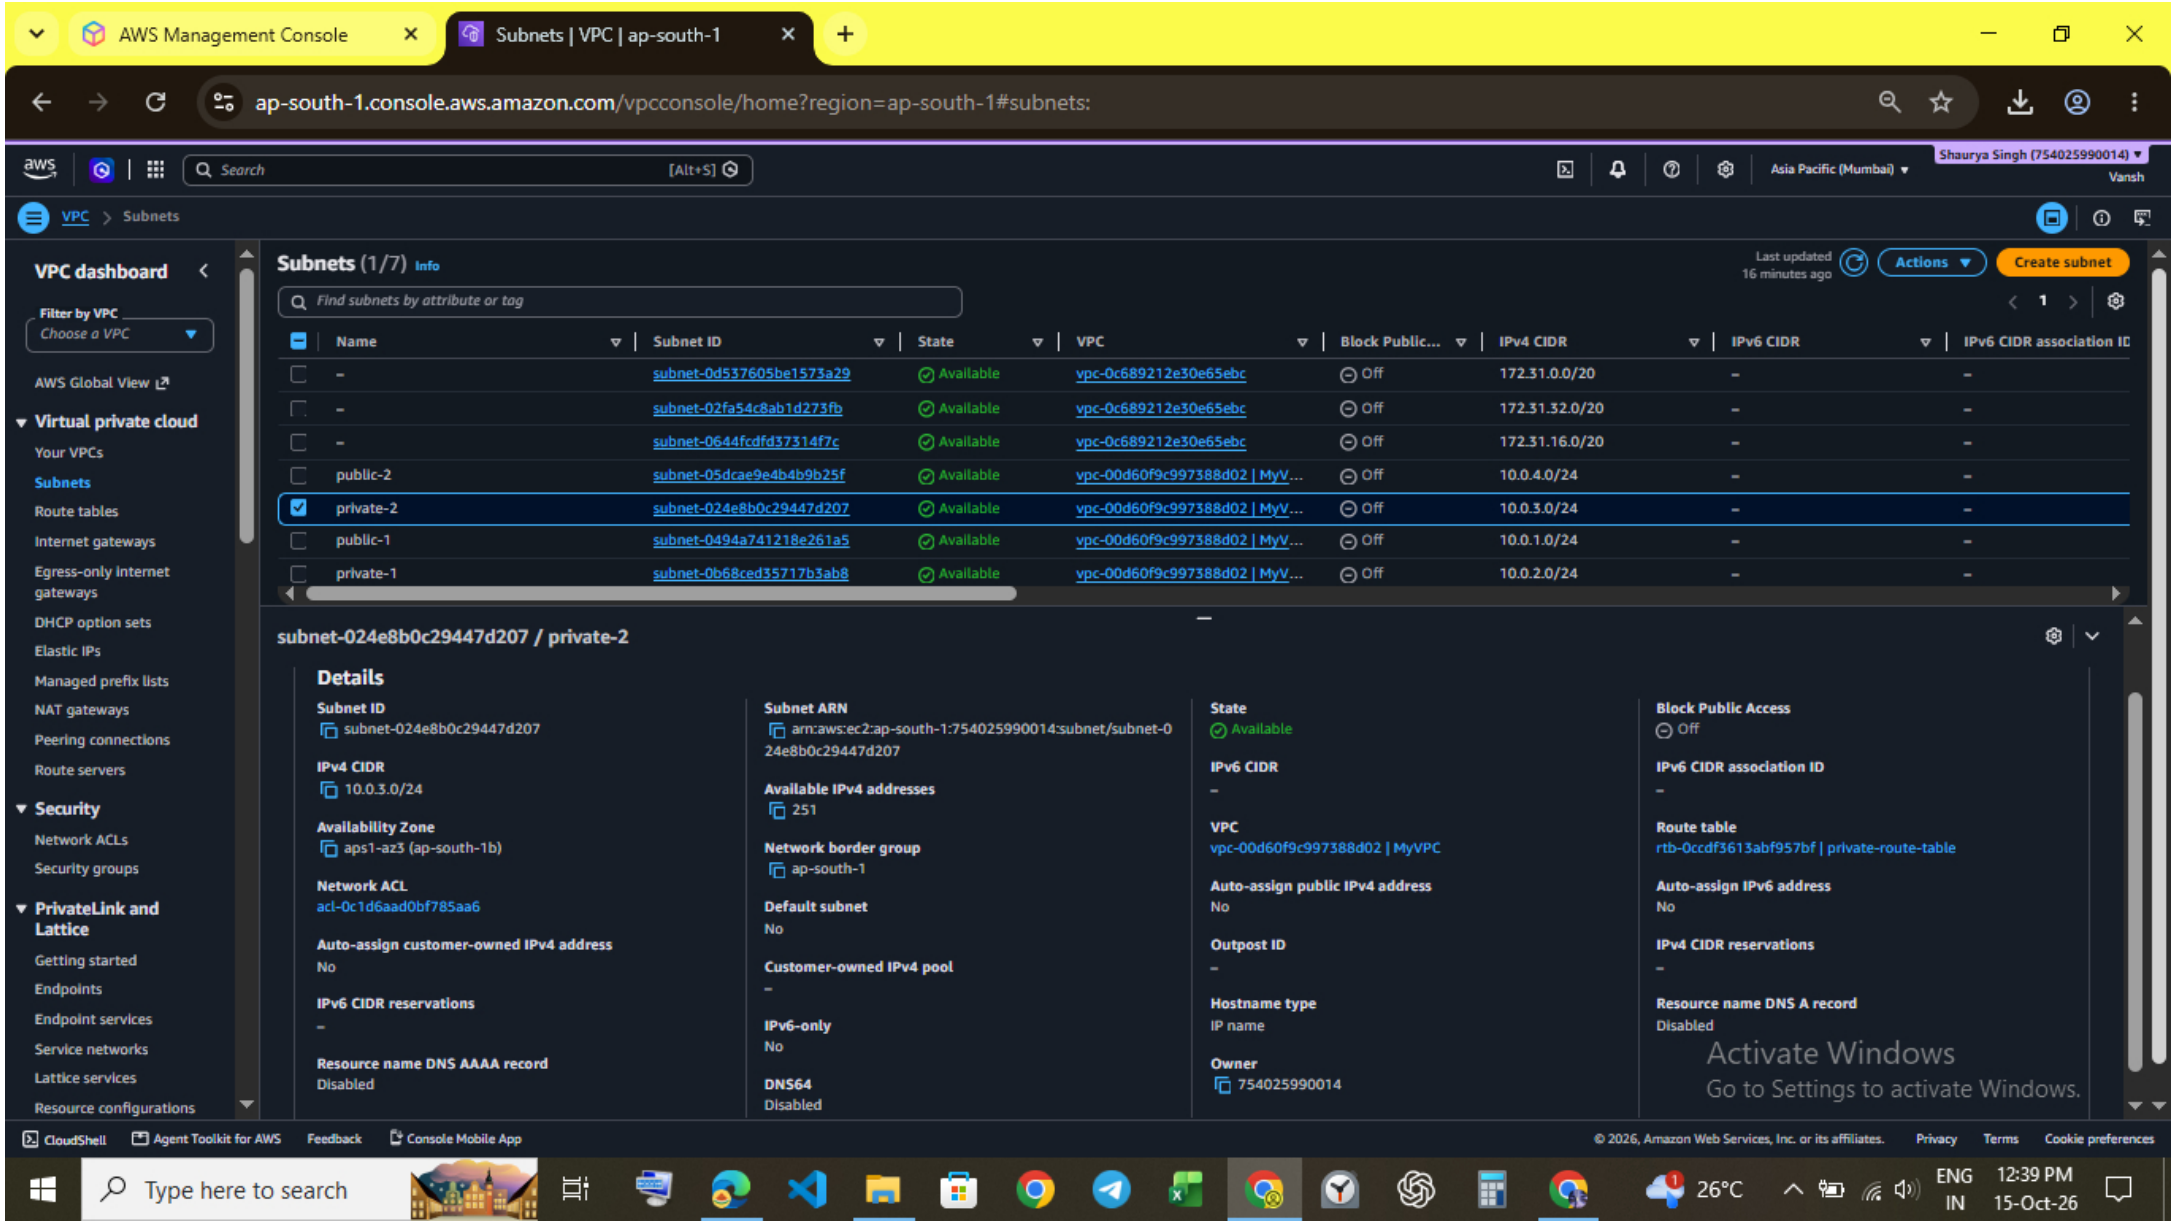

> The screenshots immediately following this phase are the original pages 1–18 of CloudShield-Final-PDF. They are retained in the same order as supplied.
